

→ Lesson 3:

Components of Docker

There are four major components:

1. Docker client and server: Docker client is accessed from the terminal and on Docker host runs the Docker daemon and registry.

2. Docker Images: is a template with instructions which is used for creating Docker containers.

3. Docker containers | A Docker image is built using a file called Docker file.

4. Docker Registry.

• Docker image is stored in a Docker hub or in a repository.

~ Syntax to create a Docker container using Docker image

Docker container create [options]
image [command] [Args...]

~ Docker Registry is an open source server-side ~~image~~ ^{source} used for hosting and distributing images

Note: Docker also has its own default registry called docker hub.

Here, images can be stored in ~~there~~ either public or private repositories.

so
1) Docker Registry is a centralized place where people store, share, and manage Docker images.
