

→ what is Docker?

Docker is an open-source technology used mostly for:

- Developing.
- Shipping
- Running Applications.

i. Developing → means writing and building software application.

ii. Shipping → sending the finished application to other computers, testers, or servers without breaking any thing.

ex:-

Have you ever said, "well it worked on my computer!" when a file or game wouldn't open on your friend's laptop?

Docker solves this, "shipping" with docker means you pack your app into a digital container,

because the container looks and acts exactly the same on every computer. it will open and run perfectly for anyone you send it.

iii. Running Applications: Actually opening, starting and using the program.

7 we will cover!

1. Docker Architecture and components
2. Containers and Registry.
3. Docker Swarm.
4. Docker compose.
5. Docker compose vs Docker Swarm.

Note: Before using/understanding docker you must have minimum 3 Operating System with Unix, windows 7 or above.
3, internet 4G or Above.

⇒ Lesson 1:

What is DevOps!

The word DevOps is simply a combination of two words:-
Dev (Development - the people who build the app) and Ops (Operations - the people who run and maintain the app).

In the past these two teams worked separately and often blamed each other when things went wrong.

DevOps is the modern way of working where both sides join hands as a team, using automation so that apps can be built.

tested, and delivered to users much faster without mistakes,

So simple :-

DevOps Koi software nh hai, balkay Kaam karne ka ek tareeka (method) hai.

Pehly zamane mai software banane wale (Developers) aur us software ko live internet par chalne wale (Operations Team) alag, alag kam karte the. Developers apni kaam ko ke op wale ko de dety the, aur agr koi app mai masla hota tha to ek closure par ilzaam lagate the.

DevOps in dono teams apas mai mila deti hai. (Development + Operations).
