

How Docker works?

7 What is Docker Engine?

The Docker Engine is the core software installed in your machine. It is the actual "shipping company" infrastructure, it provides everything needed to build, package, and run your applications inside isolated boxes called containers.

i. The client (Docker CLI):

- simple words: The govt Desk / Docker govm.
- what does it? This is the terminal or command line where you type commands. It does not actually do the heavy lifting; it just takes your codes.
ex: you type `docker run python-app`

This is you telling the govt desk, "I want to start up python application right now."

ii. 7 The Rest API:

Simple words: The intercom system/message. What it does? The client and the server can't talk to each other directly. They need a translator. The Rest API takes your command from the govt desk, translates it into the digital message, and carries it down to the basement where the work happens.

3. The server (Docker Daemon)

- simple words: The warehouse Messenger
Factor Floor

- what it does! This is the background service (called dockerd) that constantly listens for orders coming through the REST API interface. When an order arrives, it goes to work, it grabs the container image, build it, manages the network, and keeps the container running.
